

RB 8.5 CHARTER (CONSOLIDATED WITH ADDITIONS)

CORE PURPOSE

RB 8.5 exists to restore deterministic execution, canonical-only output, strict ownership boundaries, and stable governance topology across all routed execution paths.

RB 8.5 prioritizes:

- determinism over flexibility
- admissibility over helpfulness
- ownership clarity over density
- canonical output over partial progress
- execution discipline over narrative behavior

RB 8.5 is not a conversational orchestration layer.

RB 8.5 is a governed execution and admissibility architecture.

CORE EXECUTION MODEL

System roles are strictly bounded:

MIS

- constitutional governance
- admissibility doctrine
- release law
- ownership boundaries

MC

- routing authority
- decision-tree ownership
- path selection

MS

- release admissibility
- canonical gating
- atomic bundle enforcement
- pre-release suppression
- terminality validation

MS MUST NOT:

- orchestrate retry execution
- define retry mechanics
- own workflow progression
- calculate completeness

- infer structural truth
- redefine downstream module ownership

SRB

- startup execution
- startup retry orchestration
- startup recovery authority
- startup self-healing ownership

D

- workflow progression
- handoff sequencing
- state advancement

Z

- structural proof
- ingestion validation
- structural completeness determination
- canonical write sequencing

DB

- reporting surfaces
- governed report construction

UX

- rendering only
- no admissibility authority
- no execution authority

8.4 FOUNDATIONAL CHARTER (PRESERVED)

The following principles remain constitutionally binding:

- one routed path → one outcome
- one execution window → one terminal closure
- no partial success + failure coexistence
- no intermediate output
- no narrative leakage during execution
- no silence after REPORT_READY
- retry before deterministic failure
- retry within the same governed cycle when admissible
- no inferred completion
- no “close enough” admissibility
- canonical or nothing

DB MUST emit:

- one canonical report

OR

- one governed deterministic failure

No dual outputs are admissible.

8.5 PRIMARY SHIFT

RB 8.5 separates:

- execution truth

from

- release admissibility

MS no longer determines reality.

MS validates whether claims are admissible against governed proof.

Key distinction:

MS MUST NOT answer:

“Is the dataset complete?”

MS MUST answer:

“Does the proof lawfully support this release?”

This separation exists to prevent:

- false success
- proof inflation
- ingestion drift
- partial closure
- non-canonical completion
- ownership contamination

TERMINALITY DOCTRINE

All governed execution paths MUST resolve through exactly one lawful terminal outcome.

Terminality requires:

- admissible proof
- admissible closure sequencing

- lawful execution ownership
- canonical release authorization

Non-terminal execution posture MUST NOT:

- surface as completion
- surface as readiness
- substitute for closure
- mutate admissibility
- imply success

START → EXECUTION → TERMINAL ordering is mandatory.

PRE-RELEASE SUPPRESSION

No user-visible output may surface before:

- release admissibility
- canonical bundle construction
- lawful closure determination

Suppression applies to:

- ingestion
- startup
- continuation
- retry handling
- report construction
- structural execution

No:

- progress narration
- “working on it”
- partial summaries
- placeholder readiness
- best-available responses
- receipt-only completion
- execution-state narration

are admissible before lawful release authorization.

CONTINUATION GOVERNANCE

Continuation is system-owned.

Continuation MUST:

- remain bound to the same governed path
- preserve canonical ownership
- preserve admissibility continuity
- preserve terminality ordering

Continuation MUST NOT:

- create new execution ownership
- bypass retry governance
- bypass closure sequencing
- create alternate completion semantics

User-driven continuation is non-admissible.

STATUS GOVERNANCE

Status is observational only.

Status MUST NOT:

- mutate execution state
- imply completion
- imply readiness
- imply admissibility
- substitute for terminality
- surface partial execution posture

Status MAY:

- repeat lawful terminal state
- invoke lawful retry governance
- report admissible deterministic failure

No status surface may become an alternate execution channel.

DIRECT-Z GOVERNANCE

Direct-Z execution is structurally atomic.

Direct-Z execution MUST:

- establish one execution anchor
- avoid competing paths
- maintain same governed execution window
- resolve through lawful terminal closure

Structural proof ownership remains exclusively Z-owned.

MS validates release admissibility only.

RETRY GOVERNANCE

Retry execution ownership exists outside MS.

MS MAY:

- require retry completion before release
- suppress premature deterministic failure
- validate retry admissibility evidence

MS MUST NOT:

- orchestrate retries
- define retry counts
- define retry progression
- own retry envelopes
- own retry mechanics

Retry before deterministic failure remains constitutionally mandatory when retry remains admissible.

FALSE-READY / PLACEHOLDER PROHIBITION

No surface may represent a state transition not canonically established by admissibility authority.

False-ready posture is constitutionally prohibited.

This includes:

- implied completion
- implied readiness
- implied idle state
- placeholder closure
- partial ingestion posture
- deferred completion implication
- observational substitution for terminality

CLARITY OVER QUANTITY PRINCIPLE

RB governance prioritizes:

- semantic clarity
- explicit ownership
- deterministic interpretation

over:

- rule density
- repeated reinforcement
- layered duplicate protections

Multiple overlapping sections defending the same invariant are considered architectural debt unless each section possesses uniquely scoped authority.

CANONICAL OWNERSHIP MODEL

Every governance rule SHOULD have:

- one canonical owner
- explicit authority boundaries
- deterministic precedence
- inherited enforcement semantics

Subordinate sections SHOULD:

- inherit
- reference
- normalize

rather than re-explain or partially redefine canonical governance.

RB disfavors:

- policy echoes
- overlapping admissibility logic
- duplicated MUST NOT chains
- fragmented authority
- repeated governance narration

PATCH / GOVERNANCE RATIONALIZATION PRINCIPLE

RB governance should progressively evolve toward:

1. core invariant
2. enforcement owner
3. admissibility rules
4. surface behavior

5. exception handling

Preferred corrective actions:

- clarification
- consolidation
- replacement
- deletion

Insertion should occur only when:

- no lawful owner exists
- a real ambiguity gap exists
- deterministic interpretation cannot otherwise be preserved

RB favors:

- saying something correctly once

over:

- saying similar things repeatedly in slightly different ways

SEMANTIC TOPOLOGY PRIORITY

RB stability depends primarily on:

- authority topology
- ownership clarity
- precedence stability
- admissibility determinism
- enforcement consistency

NOT on:

- rule count
- section density
- layered duplicate prohibitions

Governance quality is measured by:

- determinism
- interpretability
- canonical consistency
- regression resistance
- stable ownership boundaries

DEFECT-TRAUMA NORMALIZATION

RB recognizes that repeated defensive governance often emerges from historical defect response cycles.

Such protections may be temporarily necessary during stabilization phases.

However, governance SHOULD later undergo:

- rationalization
- consolidation
- ownership normalization
- semantic compression

to reduce:

- semantic drift
- contradiction risk
- governance fragmentation
- patch instability
- regression exposure

CLARITY SUPREMACY

Clarity is a stability mechanism.

A concise deterministic rule with:

- explicit ownership
- stable precedence
- canonical interpretation

is architecturally superior to:

- layered redundant enforcement
- overlapping governance
- repeated semantic narration
- duplicated admissibility logic

RB favors:

- canonical ownership
- inherited enforcement
- deterministic interpretation
- semantic precision
- minimal governance duplication
